

Locust Control is administered by the National Department of Agriculture (Agricultural Pests Act, 1983 (Act No. 36 of 1983)).

There are four species of locusts, which are periodically recorded in outbreaks in South Africa. Of these four species, the brown locust (*Locustana pardalina*), has the most significant impact on agriculture.

WHAT TO DO WHEN LOCUST SWARMS ARE SPOTTED

- Immediately report these sightings to the National Department of Agriculture or your nearest Department of Agriculture Office.
- These first sightings form part of the Early Warning System and are therefore crucial in minimising the potential damage.
- Only persons in possession of a certificate issued by the National Department of Agriculture, which certifies that he/she has successfully completed a course in locust control, may execute locust control measures.

LOCUST LIFE CYCLE

1. The natural life span of an adult locust is 78 days.
2. A female is capable of producing more than 380 eggs during her life cycle.
3. The hatching develops through five stages over a period of 56 days, after which the locust is mature and capable of reproducing.
4. Control actions are most effective during the hopper stage, when the insects move slowly and small quantities of pesticides are required to kill them.

HABITAT

1. The brown locust is native to the semi-arid Karoo, which includes parts of South Africa and Namibia.
2. The eggs are activated by moisture and heat and will hatch 10 to 14 days after as little as 10mm of rainfall.
3. During periods of drought, the eggs may lie dormant in the soil for up to three years.
